Refractory iron deficiency

Unexplained iron deficiency

Microcytic anemia

## ABSTRACT

**Background:** Refractory or unexplained iron deficiency anemia accounts for about 15% of all cases. The endoscopic gastrointestinal workup sometimes fails to establish the cause of iron deficiency anemia and a considerable proportion of patients regardless of risk category fail to respond to oral iron supplementation. The aim of the present study was to assess the etiological role of *Helicobacter pylori* infection in adult Egyptian patients with unexplained or refractory iron deficiency anemia.

**Methods:** A case controlled study was composed of 104 iron deficiency anemia cases and 70 age- and gender-matched healthy controls. Patients were diagnosed with iron deficiency anemia according to hemoglobin, mean corpuscular volume, serum ferritin, and transferrin saturation. Upper and lower endoscopies were performed and active *H. pylori* infection was investigated by testing for the *H. pylori* antigen in stool specimens. Hematological response to *H. pylori* treatment with triple therapy together with iron therapy ( $n=32$ ) or only iron therapy ( $n=32$ ) were assessed in patients with *H. pylori* infection.

**Results:** *H. pylori* infection was more prevalent in patients with unexplained or refractory iron deficiency anemia (61.5%). Of the different hematological parameters investigated, there was a significant correlation only between *H. pylori* infection and mean corpuscular volume ( $p$ -value 0.046). Moreover, there was a significant correlation between receiving triple therapy together with iron supplementation and improvements in the hematological parameters [hemoglobin ( $p$ -value < 0.001), mean corpuscular volume ( $p$ -value < 0.001), iron ( $p$ -value < 0.001) and serum ferritin ( $p$ -value < 0.001)] compared to receiving iron supplementation alone.

**Conclusions:** Failing to test for *H. pylori* infection could lead to a failure to identify a treatable cause of anemia and could lead to additional and potentially unnecessary investigations. Furthermore, treatment of *H. pylori* infection together with iron supplementation gives a more rapid and satisfactory response.

## Introduction

Iron deficiency anemia (IDA) is a worldwide nutritional problem; it accounts for about half of the world's anemia burden with most IDA patients living in developing countries.<sup>1</sup>

Refractory or unexplained IDA accounts for about 15% of all cases.<sup>2</sup> It is a diagnostic and evaluation challenge that employs a list of exams from stool testing for parasitic infestations to full gastroenterology endoscopies.<sup>3</sup> The term 'unexplained IDA' can be applied when the endoscopic gastrointestinal workup fails to establish the cause of IDA.<sup>4</sup> On the other hand, the term 'refractory IDA' is applied to a considerable proportion of patients when they fail to respond to iron supplementation at a dose of at least 100 mg of elemental iron per day over 4–6 weeks.<sup>2</sup>

It is estimated that *Helicobacter pylori* infects the stomachs of 50% of the global population. There are variations in infection rates from one country to another with the rates being inversely correlated with the human development index.<sup>5</sup>

Without eradication treatment, *H. pylori* is likely to persist in its human host for a lifetime with a proportion of infected individuals developing peptic ulcers, gastric adenocarcinomas and/or mucosa associated lymphomas (MALT). Beyond the stomach, more than 50 extra-gastric manifestations of *H. pylori* have been reported involving a wide list of medical disorders.<sup>6</sup>

The relationship between *H. pylori* and iron deficiency was first described in 1991 as a 15-year-old boy with IDA had improved hematological parameters after *H. pylori* eradication.<sup>7</sup> The mechanisms underlying the association between *H. pylori* infection and iron deficiency are not fully understood yet. The most obvious mechanism for *H. pylori* to cause IDA is by competing for dietary iron. *H. pylori* requires higher concentrations of inorganic iron and zinc than other pathogens for *in vitro* growth, yet there is no evidence that *H. pylori* has more iron- or zinc-dependent enzymes than other bacteria.<sup>8</sup>

Data on the effect of *H. pylori* eradication on adult Egyptian patients with refractory IDA or IDA of unknown origin, a population with a high prevalence of *H. pylori*, are scarce. The objectives of this study are to evaluate the prevalence of *H. pylori* infection among a cohort of Egyptian patients with unexplained iron deficiency anemia and to investigate the relationship between *H. pylori* infection and the hematological parameters of these patients. Furthermore, this study aimed to assess the patients' response to combined *H. pylori* triple therapy with iron therapy compared to iron therapy alone.

## Methods

A total of 104 Egyptian subjects who were diagnosed with IDA of unknown cause or who were refractory to oral iron therapy (60 women and 44 men with a mean age of  $39.6 \pm 10.84$  years) and 70 age- and gender-matched healthy controls were enrolled in this study. All subjects were consecutively recruited in the Clinical Hematology Unit of the Kasr Al-Ainy Teaching Hospital, Cairo University where they were diagnosed and followed-up prospectively between October 2014 and June 2017. The study complied with good clinical practice

protocols and with the ethical norms stated in the Declaration of Helsinki (as revised in Tokyo 2004). The study was approved by the local Ethics Committee and all patients gave their written informed consent prior to recruitment.

All subjects with unexplained or refractory iron deficiency anemia as well as healthy controls were subjected to full history taking (especially nutritional and menstrual data, drugs taken, bleeding or gastrointestinal history as well as compliance to iron therapy), a thorough physical examination, and laboratory tests. The laboratory investigations included a complete blood count (CBC) and blood film, reticulocyte count, erythrocyte sedimentation rate (ESR), lactate dehydrogenase (LDH), and liver and kidney function as well as upper and lower endoscopies. Patients with malignancies, chronic diseases, dimorphic anemia, obvious causes of IDA and acute infections were excluded from the study.

### Diagnosis of iron deficiency anemia

All patients had hemoglobin levels less than reference values for age and gender with a blood film that showed microcytic hypochromic anemia. The mean corpuscular volume (MCV) was less than 80 fl, serum ferritin was below 20 ng/dL; iron was below 50 g/dL and total iron binding capacity (TIBC) was more than 350 g/dL. The transferrin saturation was below 15%. Ferritin was measured using the Elecsys 2010 system using a Roche diagnostics kit by the electro-chemiluminescence immunoassay (ECLIA) method. Serum levels of iron were measured by the colorimetric method with a Roche modular analyzer. TIBC was measured with the Roche modular analyzer.

### Diagnosis of *H. pylori* infection

Stool specimens were collected from participants (patients as well as healthy controls) and tested for the *H. pylori* antigen using the *H. pylori* Ag test (CTK Biotech, Inc. San Diego, CA 92121, USA. Cat # R0192C). This is a sandwich lateral flow chromatographic immunoassay that uses a colloidal gold conjugated monoclonal anti-*H. pylori* antibody and a second monoclonal anti-*H. pylori* antibody to specifically detect the *H. pylori* antigen present in fecal specimens. The detection limit for the spectrum *H. pylori* Ag test device is a 5 ng/mL *H. pylori* lysate.

### Therapy response assessment

Patients who were discovered to have *H. pylori* infection were randomly subdivided into two groups:

Group A: received triple therapy for *H. pylori* eradication (omeprazole 20 mg b.i.d., amoxicillin 1 g b.i.d. and clarithromycin 500 mg b.i.d.) for 14 days combined with oral iron therapy (ferrous sulphate 325 mg OD) for three months.

Group B: received only oral iron therapy (ferrous sulphate 325 mg OD) for three months.

After three months of therapy, Group A and Group B were both reassessed regarding hemoglobin, MCV, mean corpuscular hemoglobin (MCH), serum iron, and ferritin levels with *H.*

*pylori* eradication being evaluated by the detection of the *H. pylori* antigen in stools.

### Statistical analysis

Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 23. Data was summarized using means, standard deviation (SD), median, minimum and maximum in quantitative data and using absolute frequencies (count) and relative frequencies (percentage) for categorical data. Comparisons between quantitative variables were achieved using the non-parametric Kruskal-Wallis and Mann-Whitney tests. The Chi-square ( $\chi^2$ ) test was used to compare categorical data. Fisher's exact test was used when the expected frequency was less than 5. *p*-Values less than 0.05 were considered statistically significant.

### Results

The patients enrolled in this study included 60 females (63.5%) and 44 males (42.3%) with ages ranging between 19 and 65 years (mean age:  $39.6 \pm 10.84$  years). The healthy controls were 36 (51.4%) females and 34 males (48.5%) with ages ranging between 20 and 62 years (mean age:  $39.6 \pm 10.84$  years).

The duration of IDA of the patients ranged from 0.9 to 8 years (mean:  $3.8 \pm 1.6$  years); all had unexplained causes for IDA. All patients had unremarkable physical examinations and the gynecological examinations of all the women were normal. Patient characteristics are summarized in [Tables 1 and 2](#).

**Table 1 – Data of patients with refractory or unexplained iron deficiency anemia.**

Parameter	Range	Mean $\pm$ SD
Age (years)	(19–65)	$39.67 \pm 10.84$
Duration of IDA (years)	(0.9–8)	$3.83 \pm 1.66$
WBC (cells $\times 10^9$ L <sup>-1</sup> )	(4–16)	$7.5 \pm 3.4$
Hemoglobin (g/dL)	(5.8–10)	$8.08 \pm 0.99$
MCV (fl)	(59–75)	$68.1 \pm 3.89$
MCH (pg)	(17–25)	$20.04 \pm 1.73$
Platelets (cells $\times 10^9$ L <sup>-1</sup> )	(149–750)	$333 \pm 122$
Reticulocyte (%)	(0.5–4)	$2.06 \pm 0.86$
ESR (mm/h)	(10–90)	$37.71 \pm 16.38$
IRON (g/dL)	(6–40)	$22.8 \pm 10.89$
TIBC (g/dL)	(350–520)	$387 \pm 72$
TS (%)	(1–14)	$5.4 \pm 2.6$
Ferritin (ng/dL)	(1–20)	$7.7 \pm 5.3$
ALT (IU/L)	(10–50)	$30.65 \pm 18.8$
AST (IU/L)	(15–45)	$32.46 \pm 19.3$
LDH (IU/L)	(95–300)	$181.15 \pm 52.14$
ALB (mg/dL)	(3.5–5)	$3.78 \pm 0.55$
PC (%)	(72–100)	$95.81 \pm 5.3$
Creatinine (mg/dL)	(0.6–1.4)	$1.1 \pm 0.18$

SD: standard deviation; IDA: iron deficiency anemia; WBC: white blood cell count; MCV: mean corpuscular volume; MCH: mean corpuscular hemoglobin; ESR: erythrocyte sedimentation rate; TIBC: total iron binding capacity; TS: transferrin saturation; ALT: alanine transaminase; AST: aspartate transaminase; LDH: lactate dehydrogenase; ALB: albumin.

**Table 2 – Non-parametric data of patients with refractory or unexplained iron deficiency anemia.**

Parameter		n	%
Sex	Male	44	42.3
	Female	66	63.5
Previous iron therapy	Yes	74	71.1
	No	30	28.8
Previous blood transfusion	Yes	38	36.5
	No	66	63.4
Upper endoscopy	No abnormalities	66	63.4
	Mild gastritis	30	28.8
	Antral erosions	8	7.69
Colonoscopy	Normal	60	57.6
	Nonspecific colitis	44	42.3
<i>H. pylori</i> Ag in stools	Positive	64	61.5
	Negative	40	38.4

The *H. pylori* Ag test was positive in 64 out of 104 (61.5%) patients and in 10 (14.3%) non-anemic healthy controls; the difference between the two groups was statistically significant (*p*-value < 0.001; [Figure 1](#)).

Patients were sub-divided into two groups according to *H. pylori* Ag status; Group I (*H. pylori* Ag Positive) and Group II (*H. pylori* Ag negative). A correlation analysis was performed with the clinical and laboratory features as summarized in [Table 3](#); there was a significant correlation between *H. pylori* status and MCV (*p*-value = 0.046), otherwise there were no significant correlations with other parameters including the iron parameters.

Group I (*H. pylori* positive) was further randomly divided into two groups; Group A (32 patients) received triple therapy plus oral iron supplementation and Group B (32 Patients) received only oral iron supplementation. These patients were reassessed after three months. The flowchart of the study is shown in [Figure 2](#) and the data are summarized in [Table 4](#).

Group A was comprised of 14 males and 18 females while Group B consisted of 16 males and 16 females. Group A showed statistically significant improvements in the hemoglobin level,

**Figure 1 – Prevalence of *H. pylori* between unexplained-refractory iron deficiency anemia and control groups. IDA: Unexplained-refractory iron deficiency anemia group (n = 104); HC: healthy control group (n = 70). \*Mean values were significantly different between groups (*p*-value < 0.001).**

**Table 3 – Clinical and laboratory comparison between *H. pylori*-positive and -negative patients.**

Parameter	<i>H. pylori</i> status				p-Value
	Group I positive (n = 64)		Group II negative (n = 40)		
	Range	Mean ± SD	Range	Mean ± SD	
Age (years)	(19–65)	40.8 ± 11.1	(20–55)	37.8 ± 10.33	0.342
Duration of IDA (years)	(1–8)	4.06 ± 1.71	(0.9–7)	3.45 ± 1.53	0.197
WBC (cells × 10 <sup>9</sup> L <sup>-1</sup> )	(4.5–14.5)	7.6 ± 3.4	(4–16)	7.3 ± 3.6	0.588
Hemoglobin (gm/dL)	(5.8–9.9)	8.1 ± 1.02	(6.8–10)	7.9 ± 0.9	0.877
MCV (fl)	(60–73)	66.7 ± 3.5	(59.8–75)	68.9 ± 3.9	<b>0.046<sup>a</sup></b>
MCH (pg)	(17–22)	19.4 ± 1.43	(17–25)	20.4 ± 1.82	0.057
Platelets (cells × 10 <sup>9</sup> L <sup>-1</sup> )	(149–750)	334.2 ± 116.1	(160–690)	331.1 ± 135.4	0.930

<sup>a</sup> Significantly difference (*p*-value < 0.05).

**Figure 2 – Flowchart of study group. IDA: iron deficiency anemia.**

MCV, MCH, serum iron and ferritin after three months of therapy (*p*-value < 0.001, 0.001, 0.001, 0.001, 0.001, respectively). On the other hand, Group B had no statistically significant improvements in hemoglobin level, MCV, MCH, serum iron or ferritin (*p*-value: 0.083, 0.074, 0.092, 0.068 and 0.059, respectively). *H. pylori* was eradicated in all 32 patients of Group A.

## Discussion

Refractory or unexplained IDA accounts for about 15% of all IDA. It is a diagnostic challenge with evaluations that include a set of tests starting with stool testing for parasites and continuing up to full gastroenterology endoscopies. Endoscopic gastrointestinal workups sometimes fail to establish the cause of IDA and a considerable proportion of patients regardless of risk category fail to respond to oral iron supplementation.<sup>9</sup>

The prevalence of *H. pylori* is not homogenous worldwide; it varies depending on age, country of origin and socioeconomic conditions. The Egyptian Demographic Health Survey reported a prevalence of *H. pylori* infection in 6.6% of Egyptian adults.<sup>10</sup> The aim of the present study was to assess the etiological role of *H. pylori* infection in adult Egyptian patients with unexplained or refractory IDA.

This study found that *H. pylori* infection was more prevalent in patients with unexplained or refractory IDA (61.5%) compared to healthy controls (14.3%) with these results possibly suggesting that *H. pylori* infection is one cause of IDA in adult patients with unexplained or refractory IDA for whom the standard diagnostic work-up is negative. These data are corroborated by many other studies that reported high prevalences of *H. pylori* in patients with unexplained or refractory IDA. For example, Hershko et al. found that *H. pylori* infection was the common coexisting finding in 55% of 300 patients with unexplained IDA.<sup>11</sup> However, a study by Santos et al., conducted in 2149 children from Latin America did not find any significant association between *H. pylori* infection and IDA.<sup>12</sup> Furthermore, studies performed in Brazil,<sup>13</sup> South Korea,<sup>14</sup> Sweden<sup>15</sup> and Iran<sup>16</sup> were not successful in finding any significant association between the prevalence of *H. pylori* infection and IDA.

The present study only found a significant difference in MCV between *H. pylori*-positive and *H. pylori*-negative groups. It was not expected to find any other differences especially in respect to iron parameters, as for many years different studies demonstrated an association between *H. pylori* infection and decreasing iron status. Some found an association between *H. pylori* infection and decreasing ferritin levels.<sup>17</sup> A large study conducted in 1040 children in Alaska by Parkinson et al. found a significant association between low serum ferritin levels and the prevalence of *H. pylori* infection.<sup>18</sup> A German study found significantly lower levels of hemoglobin in pregnant women suffering from *H. pylori* infection.<sup>19</sup> Moreover, an American study conducted in 7462 healthy individuals found that those who were seropositive for *H. pylori* infection had significantly

<sup>a</sup> Significantly difference (p-value <0.05).

lower serum ferritin levels compared with seronegative individuals.<sup>20</sup> Even so, an Egyptian study conducted with 90 chronic kidney disease patients on hemodialysis also found no significant differences between *H. pylori*-positive and -negative groups for any of the variables analyzed including hemoglobin, serum iron, ferritin and transferrin saturation.<sup>21</sup> In addition, an Egyptian study conducted in 60 children found that the soluble transferrin receptor in serum was significantly higher in the *H. pylori*-positive group compared to the *H. pylori*-negative group although no significant differences were noted in hematologic variables and iron parameters between the two groups.<sup>22</sup> This variability in studies could be due to differences in the geographical and ethnical distribution of patients, age, inclusion criteria, sample size, sampling procedures, methods of detecting anemia, and methods of detecting *H. pylori* infection.

Regarding the therapeutic intervention, there was marked improvement in hemoglobin level, Three months of therapy had a statistically significant effect on MCV and iron parameters in the arm that combined triple therapy with oral iron supplementation compared to the arm of oral iron therapy alone. This is considered the most reliable evidence for a cause–effect relationship between *H. pylori* infection and unexplained iron deficiency. This result corroborated many other studies that showed that the eradication of *H. pylori*, with or without iron supplementation, was followed by improvements in hemoglobin levels. However, other studies did not reveal such clear improvements in the markers of iron deficiency as shown in Table 5. These studies suggested that the treatment of *H. pylori* infection is important to reduce the IDA

burden worldwide. On the contrary, one study conducted in 200 children in Bangladesh, a country with a high prevalence of *H. pylori*, found that *H. pylori* is neither a cause of IDA/iron deficiency nor a reason for failure of iron supplementation.<sup>23</sup> Furthermore, a study conducted in 18 school-aged cases of IDA with *H. pylori* infections in Saudi Arabia reported no significant improvement in serum ferritin levels with the use of anti-*H. pylori* treatment without iron supplementation.<sup>24</sup>

In conclusion, the present study suggests that there is an association between *H. pylori* infection and refractory or unexplained IDA in adult Egyptian patients. In cases of IDA and co-existing *H. pylori* infection, IDA can be treated by the eradication of *H. pylori* in combination with iron supplementation. Failing to test for *H. pylori* infection could lead to a failure to identify a treatable cause of anemia and could lead to additional and potentially unnecessary investigations. Moreover, treatment of *H. pylori* infection together with iron therapy may give a more rapid and satisfactory response.

**Table 5 – *Helicobacter pylori* associated unexplained iron deficiency anemia in comparable studies.**

Studies	Study group	<i>H. pylori</i> detection	Study design	Conclusions
El-Aziz Awad et al., Egypt [22]	Children	<i>H. pylori</i> serum IgG antibodies	Group (A): Anti <i>H. pylori</i> and Oral iron (n=20) Group (B): Anti <i>H. pylori</i> (n=20) Group (C): oral iron (n=20)	Improvement of iron parameters were significantly greater in groups of children who received anti-HP therapy either combined with iron or alone
Nashaat et al., Egypt [25]	Pregnant women	<i>H. pylori</i> serum IgG antibodies	All patients received oral iron (n=100) after 1 month <i>H. pylori</i> positive cases (n=50) received anti <i>H. pylori</i> and oral iron	Hb in cases negative to <i>H. pylori</i> was higher than those positive to <i>H. pylori</i> . It was found that rise of Hb was higher after treatment than before eradication of <i>H. pylori</i> .
Kotb et al., Egypt [26]	IDA adults	Gastric biopsy for <i>H. pylori</i>	20 patients received sequential eradication therapy for followed by oral iron therapy.	Improvement in hematological parameters and serum iron profile was observed post successful <i>H. eradication</i> and oral iron therapy.
Xia et al., China [27]	Adolescent girls	Serum <i>H. pylori</i> IgG antibodies and stool antigen EIA	Group (A): oral iron and anti <i>H. pylori</i> (n=32) Group (B): oral iron (n=42)	Treatment of <i>H. pylori</i> infection is associated with a more rapid response to oral Fe therapy
Malik et al., India [28]	Pregnant women	<i>H. pylori</i> stool antigen	Group (A): anti <i>H. pylori</i> and oral iron and folic acid (n=19) Group (B): oral iron and folic acid (n=19)	Eradication therapy resulted in significantly better response to oral iron supplementation among <i>H. pylori</i> infected pregnant women with IDA.
Cardenas et al., Texas [29]	Children (3–10) years	Urine <i>H. pylori</i> IgG antibody and <sup>13</sup> C-labeled urea breath tests	Group (A): Both anti <i>H. pylori</i> and oral iron (n=32). Group (B): anti <i>H. pylori</i> sequential (n=29) Group (C): oral Iron (n=23) Group (D): Placebo only (n=26)	They found that those who had their infection eradicated had a 3-fold increased average change from baseline serum ferritin compared with that of children who remained infected
Sarker et al., Bangladesh [23]	Children (2–5) years	<sup>13</sup> C-labeled urea breath tests	Group (A): anti <i>H. pylori</i> and oral iron (n=50). Group (B): anti <i>H. pylori</i> (n=50). Group (C): oral iron (n=49) Group (D): Placebos only (n=51)	<i>H. pylori</i> is neither a cause of IDA/ID nor a reason for treatment failure of iron supplementation in young Bangladeshi children
Vijayan et al., India [30]	13 years or older	Rapid urease test and histology	Group (A): anti <i>H. pylori</i> and oral iron (n=11) Group (B): oral iron (n=11)	Treatment for both anemia and <i>H. pylori</i> infections is required for lowering the levels of lipid peroxides in those patients.
Chen and Luo, China [31]	IDA adults	<sup>13</sup> C-labeled urea breath tests	Group (A): anti <i>H. pylori</i> and oral iron (n=43) Group (B): Oral iron (n=43)	Successful <i>H. pylori</i> eradication resulted in a significant post-treatment an increase in the peripheral complete blood count and serum iron.
Gessner et al., USA [32]	Children (7–11) years	<sup>13</sup> C-labeled urea breath tests	Group (A): anti <i>H. pylori</i> and oral iron (n=79) Group (B): oral iron (n=113)	In a high-prevalence population, treatment and resolution of <i>H. pylori</i> infection did not improve isolated iron deficiency or mild anemia up to 14 months after treatment initiation.
Choe et al., South Korea [33]	Adolescent female athletes	Rapid urease test and histology	Group (A): anti <i>H. pylori</i> (n=12) Group (B): oral iron (n=9)	Significant increases in iron parameters after <i>H. pylori</i> eradication while no significant changes in subjects who were treated orally with iron alone
Choe et al., South Korea [34]	Preadolescent children and adolescents	Rapid urease test and histology	Group A: anti <i>H. pylori</i> and oral iron. Group B: only anti <i>H. pylori</i> . Group C: only oral iron.	Treatment of <i>H. pylori</i> infection was associated with a more rapid response to oral iron treatment than the use of iron alone

## Acknowledgments

We deeply thank all of our patients who accepted to participate in this study. In addition, we thank Dr. Mohamed Ali Eshra, Lecturer of Human Physiology, Faculty of Medicine, Cairo University, for his meticulous statistical work.
