ABSTRACT

The oral involvement in the Hematopoietic Stem Cell Transplantation is well described in the literature. The goal of the dental treatment and management of the oral lesions related to the HSCT is to reduce the harm caused by preexisting oral infection or even the worsening of oral acute/chronic GVHD and late effects. The aim of this guideline was to discuss the dental management of patients subjected to HSCT, considering three phases of the HSCT: pre-HSCT, acute phase, and late phase. The literature published from 2010 to 2020 was reviewed in order to identify dental interventions in this patient population. The selected papers were divided into three groups: pre-HSCT, acute phase, and late phase. The literature published from 2010 to 2020 was reviewed in order to identify dental interventions in this patient population. When necessary, an expertise opinion was considered for better translating the guideline recommendations to our population dental characteristics. This manuscript focused on the pre-HSCT dental management. The objective of the pre-HSCT dental management is to identify possible dental situations that
Introduction

HSCT-related oral complications is recognized in the literature and is estimated to be present in about 80% of patients undergoing this therapeutic modality.1-4 These oral complications can directly impact complications and the patient’s quality of life during HSCT.4-9

The management of the oral cavity in patients undergoing HSCT is of utmost importance.5,10 This management can be subdivided into three stages: pre-HSCT; during HSCT, and late phase of HSCT.5 Each phase has specific characteristics in terms of oral complications and oral management. Thus, the importance of pre-existing oral infections in the pre-HSCT phase, the oral assessment during oral complications in the initial phase, and the diagnosis and management of chronic oral/dental complications in the late phase have been discussed.5,10

In the light of the reports, a group of oral medicine experts was invited by the Brazilian Society of Cellular Therapy and Bone Marrow Transplantation (SBTMO) to develop a guideline for HSCT patients’ dental care, taking into consideration the oral health characteristics of the Brazilian population.

Therefore, this is the first in a series of 3 articles that will discuss the dental management of the HSCT population. These manuscripts intend to provide continuing education to fellow dental surgeons on this specific area of care and, consequently, to facilitate HSCT patient’s access to dental care.

Objective

The aim of this positioning manuscript was to provide recommendations by the Dental Committee of the Brazilian Society of Bone Cell Transplantation (SBTMO) for basic oral health-care and dental treatment for patients undergoing the HSCT.

This article intends to detail the specific management guideline of various dental conditions that should be considered before the HSCT.

Review methods

A narrative review was conducted on the database MEDLINE/PubMed and Embase. The primary outcome was to retrieve original data on relevant articles containing dental protocols in patients undergoing the HSCT. All original studies in English, Spanish or Portuguese assessing oral health, oral complications and dental procedures in adult and pediatric patients subjected to HSCT were reviewed by the group of oral medicine experts. Manuscripts written in different languages other than the ones mentioned above, conference abstracts, case reports, and articles including solid tumors were excluded.

The panel of experts reviewed the selected articles and then discussed the most important aspects involving oral health through virtual meetings. Thus, the recommendations in these 3 steps guide was obtained based on literature data and on the experts’ clinical experience.

The articles and the experts were divided into three groups: 1. Oral care before HSCT (oral preparation for HSCT); 2. Oral care during HSCT (until neutrophil engraftment) and 3. Special topics on oral health.

For this first article, the search strategy combined all key terms for HSCT, including the key terms separately or in combination: management, dental, oral, tooth, procedures, prophylaxis and surgery, health, Brazil, infection, submucosal scaling, periodontal and dentoalveolar surgery, endodontic, restorative, and orthodontic treatment published from the period of January 2010 to December of 2020 (Figure 1).

Review/results

General consideration

The objective of pre-HSCT dental management is to minimize risks of dental origin infections that may increase the patient’s morbidity, during the first 100 days of HSCT.11-13 It is important to establish good communication between the transplant team and the dental group for the patient’s best care. Dental treatment planning requires that the dentist (oral medicine) understands the basic principles of the

Figure 1 – Flowchart of the study.
diseases that lead to HSCT and the different treatment protocols involved in patient’s care (Figures 2 and 3). Ideally, an initial dental appointment should be scheduled as soon as possible to allow sufficient time for the dental treatment needed and to give time for tissues to heal after surgical procedure, preferably with a healing period of 2 to 3 weeks after the completion of the dental treatment (Figure 2).

Previous dental assessment is indispensable regardless the time available for transplantation.

In mouth preparation, the resolution of infection foci must be prioritized. The indication of a surgical procedure out of the ideal time for healing should be discussed according to each case. Nevertheless, time constraints and patients medical condition may require modification of the dental treatment plan (Figure 3).

Elective additional dental needs identified in pre-HSCT examination should be postponed to when the patient’s overall health status allows it.

**Special considerations**

Laboratory tests, such as blood count and platelets count, should be performed before dental treatment, mostly if the patient was underdoing any treatment that could increase

---

**Figure 2 – Flowchart for initial dental appointment.**

**Figure 3 – Flowchart for proposing a dental treatment plan before HSCT.**

Abbreviations: ATB- antibiotic.
the risk of bleeding or the risk of systemic and/or local infection. Other blood exam such coagulation screening should be performed in those patients which may present coagulation disorders.17

Antibiotic prophylaxis (AP), antibiotic treatment (AT), and the dental treatment plan need to be carefully discussed between the medical, dental, and multidisciplinary team before the dental treatment. The discussion should consider the underlying disease status, the current patient’s immune status, and the risk of the dental procedure for local or systemic infection.13,17,18 (Table 1)

Dental management

1 – Basic oral care

The maintenance of oral hygiene, through tooth brushing, must be reinforced and maintained throughout the HSCT period. It has been reported the beneficial effect of chlorhexidine mouthwash use in association with tooth brushing on the reduction of gingival inflammation.19,20 Therefore, chlorhexidine mouth wash should be recommended as an auxiliary therapy in periodontal treatment.20,21 Chlorhexidine can also be recommended for biofilm control for those patients who present exposed necrotic bone.19,22

The anticariogenic benefits of fluoride therapy is well documented in the literature.23 Compromised oral health, high caries risk, alteration of caries-related factors, and dysbiosis of oral microbiota were related to cancer treatment in children24 and in patients who underwent HSCT.25-27 These findings may be critical to the development of strategies for personalized preventive management of dental caries for this patient population.24

2 – Dental assessment

2.1 – Periodontal treatment – the presence of periodontal disease has been considered a risk condition for local and systemic infection and local bleeding complications in the first 100 days of HSCT.28-31 It is important to establish a routine periodontal screening in order to facilitate the treatment planning as well as the periodontal follow-up in this patient population.29 In this article, Periodontal Screening & Recording (PSR)32 was used as a guidance method for comprehensive periodontal assessment. The recommendations for periodontal management based on the PSR criteria, the risk for local or systemic complication of the previous periodontal condition to the initial phase of the HSCT, and the timing for its execution and tissue healing were detailed in Table 1.

2.2 – Caries treatment – restorative treatment usually does not represent a risk of complication for these patients. Extensive dental caries with potential endodontic involvement can represent a risk for pulpitis and infection.13,33 Some dental conditions, such sharper broken dental crown, can represent risk for mucosal injury mostly during the mucositis period. These situations should be managed before the HSCT (Table 1).

2.3 – Exodontia – dental extraction represents risk of local/systemic infection and bleeding. As well as in all invasive dental treatment, special concern about the risk of infection and bleeding must be part of the dental assessment plan and must be discussed with the medical team. Proper attention should be devoted to those patients who present risk of developing osteonecrosis of the jaw regarding the use of antibiotics prophylaxis.34-36 Other clinical situations, such as residual root, which require invasive approaches are detailed in Table 1.

2.4 – Third Molar – third molar extraction can present a high incidence of complications37 that might impair the HSCT schedule. In this guideline, third molar extraction was recommended for symptomatic non-erupted and semi-erupted third molar or for those patients at high risk of developing chronic GVHD. It is mandatory to consider the timing for complete wound healing before the HSCT conditioning regimen initiation. If there is not available healing time, consider non-invasive management. (Table 1)

2.5 - Endodontic treatment – due to the different endodontic treatment needs and the uncertainty of the time required for apical sterilization, there is a discussion on the literature focusing on the risk of acute infection reactivation during the immunosuppression period of HSCT.13,33 In this guideline, the recommendation for endodontic treatment took into consideration the presence of signs or symptoms of infection and, within the required timeframe for the HSCT initiation. (Table 1)

2.6 - Orthodontic appliance – orthodontic appliances can impair the oral basic care and raise the risk of mucosal harm, mostly during the oral mucositis period.38 In this guideline, the recommendation is to avoid the use of removable appliances and withdraw the fixed orthodontic apparatus before the initiation of the conditioning regimen up to day 100 of the HSCT (Table 1).

2.7 – Children Patients – for the pediatric HSCT population, the dental planning should take into consideration the same rationale described above in terms of basic oral care, good relationship between the medical and dental team, and dental management strategies. However, the recommendation for oral hygiene, including toothbrushing technique and mouthwash, should be personalized based on the children age and the motor coordination.23-26 The dental approach for deciduous teeth must consider the degree of the decidual root resorption and the degree of the permanent root growth (Table1).40

Discussion and conclusion

The development of a guideline of dental care addressed to patients to be subjected to HSCT, aligned with the population characteristics of oral health in our country, provides tools to general dentists and oral medicine professionals in providing a safe dental treatment to this particular group of patients.

The last oral health survey conducted by the Brazilian Ministry of Health44 showed that periodontal disease, as well as dental caries, are the oral infections of the highest prevalence and incidence in our population. These findings have been observed since childhood and are perpetuated into adulthood, probably being responsible for the high incidence of edentulous adults (>60 years) in Brazil.44

*Hematol Transfus Cell Ther. 2023; 45(3):358–367*
The impact of pre-HSCT dental treatment on the early phase events of HSCT, such as oral mucositis, is not well determined in the literature. However, it is common sense that oral cavity preparation, as well as the removal of infectious foci, should be performed in these patients to decrease the risk of developing local and/or systemic infections of odontogenic origin.

A study carried out in a Brazilian tertiary service found a high incidence of periodontal (33%) and endodontic (15%) foci, and active caries (27%) in pre-transplant patients. In the same study, oral diseases and poor oral health indices were more frequent in children and young people with chronic hematologic diseases. About 50% of these patients showed some necessity for dental intervention before HSCT.

These findings have been corroborated by studies published in the literature. In Brazil, not every Bone Marrow Transplant Service has a dentist as a member of the multidisciplinary team. In these situations, patients need to be evaluated by dentists working in public dental services or in private practices, where the professionals may not be familiar with the particularities of dental care for this specific group of patients. This guideline was written taking into consideration the characteristics of dental conditions observed in the clinical routine of the Dentistry services of the Transplant Centers in Brazil, and the most frequent dental conditions of the Transplant Centers in Brazil. The details of the procedures described here considered the general health conditions of the patient and the time between the end of the dental treatment and the beginning of the HSCT emphasizing the importance of the close work between the dentist and the multidisciplinary team. We hope to facilitate the patient's access to safe and effective dental treatment.

Statement of clinical relevance

The complications in the oral cavity may increase mortality and morbidity in the different phases of the hematopoietic stem cell transplantation. There is not a Brazilian guideline that guides the work of dentists with patients subjected to HSCT. This first part of the consensus offers guidance towards pre-HSCT dental intervention.

* For mouth preparation, resolution of infectious foci must be prioritized. The indication of surgical procedure out of the ideal time for healing must be discussed according to each case. All surgical manipulations must consider the potential risks of bone necrosis of the maxillaries due to previous exposure to radiation therapy or induction drugs.
